# Package 'coastMDT'

June 15, 2017

,
Title Estimate a Coastal MDT Based on Various Input Files
Version 0.0.1
<b>Date</b> 2017-03-01
Author Karina Nielsen, Ole B. Andersen, Per Knudsen, Christopher W. Hughes, and Mederic Gravell
Maintainer Karina Nielsen <karni@space.dtu.dk></karni@space.dtu.dk>
Description Estimate the coastal MDT. Altimetry data and tidegauge data is combined to form an improved coastal MDT. The software package coastMDT was developed as part of the deliverable D4 in the ESA STSE project ``GOCE++ Dynamic Topography at the coast and tide gauge unification (DYCOT)". More information regarding the projects are found in the project deliverables D1-D12 which are (or will be) from the project web page http://gocehsu.eu/. Installation instructions are found in the tutorial ``coastMDT_tutorial.pdf" available from https://github.com/cavios/coastMDT/tree/master/doc.  License GPL-2  Imports ncdf4, fields, FNN, raster, sp, akima, parallel

compareWithTG

Extract MDT values at TG positions

# Description

The function extracts MDT values at the position of the tide gauges, and compares the MDT values of the field with MDT values based on the tide gauges.

# Usage

Index

```
compareWithTG(TG, dat, lonlim, latlim, boxlon = 3, boxlat = 3,
  export = FALSE, tgfile = "TGcompare.csv")
```

# Arguments

TG	Data frame or matrix with tide gauge information. TG should contain at least the columns with the names 'Longitude', 'Latitude', and 'TGMDT'. 'TGMDT' should contain MDT values at the tide gauge positions.
dat	An object as returned by the function 'getSubGrid' or 'iterativeAveSmoother', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes).
lonlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.

ellipsoidTF2MT 3

latlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
boxlon	The number $((2 \times boxlon) + 1)$ of grid cells in the longitude direction, that is used to estimate the altimetry based MDT value at the coast.
boxlat	The number $((2 \text{ x boxlat}) + 1)$ of grid cells in the latitude direction, that is used to estimate the altimetry based MDT value at the coast.
export	If true the information estimated in the function is saved in a csv file. The default name is "TGcompare.csv". The file contains; All columns in the data frame TG,Alt_mean MDT,MDT_Alt_sd,bias corrected difference (alt-TG_bias_corr).
tgfile	a character string giving the name of the file.

#### **Details**

Besides the list, that is returned. A plot of the difference between the altimetry and the tide gauges MDT values is automatically generated

#### Value

A list that includes: mean: The mean values of the field in the box, defined by boxlon and boxlat at each tide gauge position. sd: The standard deviation of the field in the box, defined by boxlon and boxlat at each tide gauge position. bias: The bias between the mean field values and the tide gauge MDT values. diff: The difference between the mean field values and the bias corrected tide gauge MDT values RMS: The RMS of the mean field values and the tide gauge MDT values

ellipsoidTF2MT	Function that estimates the correction to go from a tide free ellipsoid
	to a mean tide ellipsoid.

#### **Description**

Function that estimates the correction to go from a tide free ellipsoid to a mean tide ellipsoid.

# Usage

```
ellipsoidTF2MT(phi, h2 = 0.62)
```

#### **Arguments**

phi	The latitude in degrees.
h2	Love number, the default value is h2=0.62

#### **Details**

...

#### Value

An array with the height differences in meter.

4 getCoastLine

getBoxMean	Helper function: Find mean valu	ie in a box

# Description

Helper function: Find mean value in a box

# Usage

```
getBoxMean(dat, id, boxlon = 4, boxlat = 4)
```

# Arguments

dat	Matrix[lon,lat] with MDT values
id	Matrix[N,2] with row and column id, reprecenting the center of the box
boxlon	Integer. The number $((2 \text{ x boxlon}) + 1)$ of grid cells in the longitude direction, that is used to estimate the altimetry based MDT value at the coast.
boxlat	Integer. The number $((2 \text{ x boxlat}) + 1)$ of grid cells in the latitude direction, that is used to estimate the altimetry based MDT value at the coast.

#### **Details**

•••

#### Value

list with mean and sd values

-	elper function to getLandVal: ask	Extract the coast line from the land
---	--------------------------------------	--------------------------------------

# Description

Helper function to getLandVal: Extract the coast line from the land mask

# Usage

```
getCoastLine(mask, land = 0, water = 1)
```

# Arguments

mask	Matrix[lon,lat] with land mask values.	
land	Integer value for land. Default is 0.	
water	Integer value for land. Default is 1.	

getCount 5

#### **Details**

...

#### Value

List with the elements; matrix g[lon,lat], which contains the location of the land value which has a water neighbor. Matrix id which contains two columns; row no and col no of the matrix g where a land value is identified as coast.

getCount

Helper function for the bootstrap function getError

# Description

This function returns a matrix with the number of times each element must be counted.

#### Usage

```
getCount(IMat, nr, nc)
```

# **Arguments**

IMat a matrix that divides the area into sub areas. It is the output of the
---

getIdMat.

nr the number of rows in the data matrix (the raw MDT).

nc the number of columns in the data matrix (the raw MDT)

#### **Details**

...

#### Value

matrix[lon,lat] where each element represents the number of times each elements should be counted in the iterative filter, when the sd is estimated for the filtered MDT, by the use of bootstrap.

6 getError

	_		
aet	Da	t.	а

Function to download data from the web

# Description

Function to download data from the web

# Usage

```
getData(localdir = tempdir(), files = NULL,
    url = "https://raw.githubusercontent.com/cavios/coastMDT/master/data/files/")
```

#### **Arguments**

localdir	A character string with the name of the directory where the data will be stored. If no name is given the data is automatically stored in a temporal directory.
files	A character vector with the names of the files to be downloaded. If not specified all data for the coastMDT package is downloaded.
url	A character string with the url, that specifies where the data is located. If not specified, the url is where the data for the coastMDT package is located.

#### **Details**

•••

getError

Estimate a MDT error field via bootstrap

# Description

With the function getError it is possible to estimate an MDT error field via the bootstrap approach.

#### Usage

```
getError(dat, land, mask, bootNr = 100, nnx = 3, nny = 3,
ncores = detectCores())
```

#### Arguments

dat	An object as returned by the function 'getSubGrid' or 'iterativeAveSmoother', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes).
land	Matrix[lon,lat] containing land values

getIdMat 7

mask	An object as returned by the function 'getSubGrid', which includes a list con-
	taining a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes).
	mask\$g is a Matrix[lon,lat] representing the land mask, where land=0 and wa-

ter=1.

nnx number of grid cells in the east-west direction
nny number of grid cells in the north-south direction

ncores Number of available cores

dat An object as returned by the function 'getSubGrid', which includes a list con-

taining a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes).

The matrix dat\$g[lon,lat] containes the values to be filtered.

#### **Details**

The data is sampled in blocks, which size is specified by the user in the arguments nnx and nny. nnx and nny should be chosen carefully. If nnx and nny are too small the data will not be independent and the error will be underestimated. If too large, there will be data gabs and the errors will not be representative.

getIdMat	Helper function for getError

#### **Description**

The function getIdMat divides a matrix into sub matrices specified by the arguments nnx and nny.

#### Usage

```
getIdMat(mask, nnx, nny, nr, nc)
```

#### **Arguments**

mask	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes). mask\$g is a Matrix[lon,lat] representing the land mask, where land=0 and water=1.
nnx	number of grid cells in the east-west direction
nny	number of grid cells in the north-south direction
nr	number of rows in the data matrix
nc	number of columns in the data matrix

#### Value

List with the elements; matrix[lon,lat] Mat (ids of the submatrices), vector mysamples (the values of the ids), and nrSam (the length of mysamples).

8 getLandComb

and animen y	getLandComb	Helper funtion to getLandVal: Finds land values based on tide gauges and altimetry
--------------	-------------	--

# Description

Helper funtion to getLandVal: Finds land values based on tide gauges and altimetry

# Usage

```
getLandComb(polyCoast, TG, TGcorr, dat, lonlim, latlim, boxlon = 4,
boxlat = 4)
```

# Arguments

polyCoast	Matrix[lon,lat], the out put of the function polygonizeCoast. The matrix contains the coastlines of the region defined by lonlim and latlim, where the integer values represents the coast id.
TG	Data frame or matrix with tide gauge information. TG should contain at least the columns with the names 'Longitude', 'Latitude', and 'TGMDT'. 'TGMDT' should contain MDT values at the tide gauge positions.
TGcorr	Vector with bias corrected tide gauge values. Obtained from the helper function getTGVal.
dat	Matrix[lon,lat] with MDT values
lonlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
latlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
boxlon	Integer. The number $((2 \text{ x boxlon}) + 1)$ of grid cells in the longitude direction, that is used to estimate the altimetry based MDT value at the coast.
boxlat	Integer. The number $((2 \text{ x boxlat}) + 1)$ of grid cells in the latitude direction, that is used to estimate the altimetry based MDT value at the coast.

# **Details**

...

#### Value

Matrix[lon,lat] with MDT land values at the coast line, defined by polyCoast

getLandInfo 9

getLandInfo	Helper function to getLandVal: coastline based on altimetry	Estimate land MDT values at the
	·	

# Description

Helper function to getLandVal: Estimate land MDT values at the coastline based on altimetry

# Usage

```
getLandInfo(mycoast, mask, dat, boxlon = 4, boxlat = 4)
```

# Arguments

mycoast	Matrix[N,2] with row and column values of the coast line. mycoast is the out put of helper function getCoastLine
mask	Matrix[lon,lat] representing the land mask, where land=0 and water=1
dat	Matrix[lon,lat] with MDT values
boxlon	Integer. The number $((2 \text{ x boxlon}) + 1)$ of grid cells in the longitude direction, that is used to estimate the altimetry based MDT value at the coast.
boxlat	Integer. The number $((2 \text{ x boxlat}) + 1)$ of grid cells in the latitude direction, that is used to estimate the altimetry based MDT value at the coast.

#### **Details**

•••

#### Value

Matrix[N,4]; row id, col id, mean MDT value, sd of MDT

getLandVal Estimates MDT land values based based on altimetry, tide gauges of both
--

# Description

Estimates MDT land values based based on altimetry, tide gauges of both

# Usage

```
getLandVal(dat, mask, lonlim, latlim, TG = NULL, type = "alt",
  intMethod = "lin", boxlon = 4, boxlat = 4)
```

10 getSubGrid

# Arguments

dat	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes).
mask	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes). mask\$g is a Matrix[lon,lat] representing the land mask, where land=0 and water=1.
lonlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees
latlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees
TG	Data frame or matrix with tide gauge information. TG should contain at least the columns with the names 'Longitude', 'Latitude', and 'TGMDT'. 'TGMDT' should contain MDT values at the tide gauge positions.
type	Character string representing the data to be used when the land values are estimated. type="tg": tide gauge data is used to estimate the MDT land values, type="alt": altimetry data is used, and type="both": both altimetry and tide gauge data is used.
intMethod	Character string describing the interpolation method used. "lin": linear interpolation and "nn": nearest neighbor interpolation
boxlon	Integer. The number $((2 \text{ x boxlon}) + 1)$ of grid cells in the longitude direction, that is used to estimate the altimetry based MDT value at the coast.
boxlat	Integer. The number $((2 \times boxlat) + 1)$ of grid cells in the latitude direction, that is used to estimate the altimetry based MDT value at the coast.

# **Details**

•••

#### Value

Matrix[lon,lat] with land values

# Description

Extract sub grid

# Usage

```
getSubGrid(grid, lonlim, latlim, res = 0.125, glonlim = c(0 + (res/2), 360 - (res/2)), glatlim = c(-90 + (res/2), 90 - (res/2))
```

getSubTG 11

# Arguments

grid	Input grid[longitude,latitude] of type matrix.
lonlim	Vector of length two containing the longitude limits of the sub grid. The limits must be given with the smallest longitude first for example $c(270,300)$ , except when the 0 longitude id crossed. In this case for example $c(355,10)$ . Acceptable values are between 0 and 360.
latlim	Vector of length two containing the latitude limits of the sub grid.
res	The resolution of the input grid in decimal degrees.
glonlim	Vector of length two containing the longitude limits of the input grid. The default is $c(0,360)$ .
glatlim	Vector of length two containing the latitude limits of the input grid. The default is $c(-90,90)$ .

#### Value

List with the elements; matrix g (sub grid), vector lon (longitudes), vector lat (latitudes) ##' @details ...

# **Examples**

```
## Not run: data(landmask8)
out<-getSubGrid(landmask8,c(280,300),c(30,60))
image(out$lon,out$lat,out$g)
## End(Not run)</pre>
```

getSubTG

Find subset of tide gauges

#### Description

Find subset of tide gauges

# Usage

```
getSubTG(TG, lonlim, latlim)
```

# **Arguments**

TG	Data frame or matrix with tide gauge information. TG should contain at least the columns with the names 'Longitude' and 'Latitude'.
lonlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
latlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.

#### Value

subset of TG

12 getTGid

getTGCoast	Helper function to getLandVal: Identify Coast lines with tide gauges
geerdeoabe	The per function to get Dana vai. Taching y coust times with true gainges

# Description

Helper function to getLandVal: Identify Coast lines with tide gauges

# Usage

```
getTGCoast(polyCoast, TG, lonlim, latlim)
```

# Arguments

polyCoast	Matrix[lon,lat], the out put of the function polygonizeCoast. The matrix contains the coastlines of the region defined by lonlim and latlim, where the integer values represents the coast id.
TG	Data frame or matrix with tide gauge information. TG should contain at least the columns with the names 'Longitude', 'Latitude', and 'TGMDT'. 'TGMDT' should contain MDT values at the tide gauge positions.
lonlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
latlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees

#### **Details**

•••

#### Value

Vector with coast id for the tide gauges.

getTGid	Helper function: Finds row and col id of Tide gauges	

# Description

Helper function: Finds row and col id of Tide gauges

# Usage

```
getTGid(TG, lonlim, latlim)
```

getTGVal 13

# Arguments

TG	Data frame or matrix with tide gauge information. TG should contain at least the columns with the names 'Longitude', 'Latitude', and 'TGMDT'. 'TGMDT' should contain MDT values at the tide gauge positions.
lonlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
latlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.

#### Value

Matrix[N,2] with row and coulmn id for the tide gauges

getTGVal Helper function to getLandVal:	getTGVal	Helper function to getLandVal:	
---	----------	--------------------------------	--

# Description

Extract MDT values at TG positions and estimates a potential bias between the tide gauges and the model based MDT.

# Usage

```
getTGVal(TG, dat, mask, lonlim, latlim, boxlon = 4, boxlat = 4)
```

# Arguments

TG	Data frame or matrix with tide gauge information. TG should contain at least the columns with the names 'Longitude', 'Latitude', and 'TGMDT'. 'TGMDT' should contain MDT values at the tide gauge positions.
dat	Matrix[lon,lat] with MDT values
mask	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes). mask\$g is a Matrix[lon,lat] representing the land mask, where land=0 and water=1.
lonlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
latlim	Vector of length 2 with the longitude data grid limits, c(lonlim[1],lonlim[2]). The limits must be given in whole degrees.
boxlon	Integer. The number $((2 \text{ x boxlon}) + 1)$ of grid cells in the longitude direction, that is used to estimate the altimetry based MDT value at the coast.
boxlat	Integer. The number $((2 \text{ x boxlat}) + 1)$ of grid cells in the latitude direction, that is used to estimate the altimetry based MDT value at the coast.

14 grid2file

#### **Details**

...

#### Value

list(TGland=out,bias=bias). TGland is data frame with 4 columns; row id, col id, corrected tide gauge value, sd of boxmean value of modeled MDT

grid2file

Write a grid[lon,lat] to a netcdf file

# Description

This function grid2file saves a grid[lon,lat] to a netcdf file.

# Usage

```
grid2file(grid, varname = "MDT", filename = "grid.nc")
```

#### Arguments

grid An object as returned by the function 'iterativeAveSmoother', which includes

a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat

(latitudes).

varname A string containing the name of the variable, the default is 'MDT'

filename A string containing the file name, the default is 'grid.nc'

# **Details**

...

# **Examples**

```
## Not run:
grid2file(boxTG_ALT, filename='MDT_filtered.nc')
## End(Not run)
```

iterativeAveSmoother 15

iterativeAveSmoother

Iterative box filter

# Description

The function iterativeAveSmoother is a simple average filter applied nit number of times. The size of the filter in the E-W direction is scaled according to the latitude.

# Usage

```
iterativeAveSmoother(dat, mask, land, radius = 0.15/0.83, nit = 10,
  res = 0.125)
```

# Arguments

dat	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes). The matrix dat\$g[lon,lat] containes the values to be filtered.
mask	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes). mask\$g is a Matrix[lon,lat] representing the land mask, where land=0 and water=1.
land	Matrix[lon,lat] containing land values
radius	Filter radius. Default is radius=0.15/0.83
nit	Number of iterations of the box filter. Default is nit=10
res	Grid spacing of the matrix dat. Default is dlat=0.125

#### **Details**

...

#### Value

List with the elements; matrix[lon,lat] g (grid), vector lon (longitudes), vector lat (latitudes).

iterativeAveSmootherBoot

Iterative box filter

# Description

The function iterativeAveSmoother is a simple average filter applied nit number of times. The size of the filter in the E-W direction is scaled according to the latitude.

# Usage

```
iterativeAveSmootherBoot(dat, mask, land, radius = 0.15/0.83, nit = 10,
  res = 0.125, countMat = NULL)
```

# Arguments

dat	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes). The matrix dat\$g[lon,lat] containes the values to be filtered.
mask	An object as returned by the function 'getSubGrid', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes). mask\$g is a Matrix[lon,lat] representing the land mask, where land=0 and water=1.
land	Matrix[lon,lat] containing land values
radius	Filter radius. Default is radius=0.15/0.83
nit	Number of iterations of the box filter. Default is nit=10
res	Grid spacing of the matrix dat. Default is dlat=0.125
countMat	A matrix where each element represent the number of times each element i the data matrix "dat" should be counted.

#### **Details**

••

#### Value

List with the elements; matrix[lon,lat] g (grid), vector lon (longitudes), vector lat (latitudes).

plotMDT 17

plotMDT	Plot MDT grid

#### **Description**

Plot MDT grid

#### Usage

```
plotMDT(dat, zlim, addContour = TRUE, conlev = 0.05, TGdat = NULL,
  legendUnit = "m", ...)
```

# Arguments

dat	An object as returned by the function 'getSubGrid' or 'iterativeAveSmoother', which includes a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes).
zlim	Range of the MDT values given as a Vector of length 2.
addContour	Bolean; To add a contour plot. Default is TRUE
conlev	The spacing between contour lines given in meters. The default is 0.05.
TGdat	MDT tide gauge data file. The file TGdat must contain at least the columns; Longitude, Latitude, TGMDT. The default is NULL.
• • •	Additional arguments to image.plot from fields

#### **Details**

•••

polygonizeCoast

Helper function to getLandVal: Turns land mask matrix into polygons

#### Description

Helper function to getLandVal: Turns land mask matrix into polygons

#### Usage

```
polygonizeCoast(mask, landVal = 0)
```

#### **Arguments**

mask Matrix[lon,lat] with land mask. Land=0 (default) and water=1.

landVal integeer representing the land value in the mask

#### Value

Matrix[lon,lat] whith coast line ids ##' @details ...

18 readRegGridBin

readncdf1var

Read net cdf file with one variable

# Description

This function readncdflvar .......

#### Usage

```
readncdf1var(filename)
```

#### **Arguments**

filename

String containing the filename

#### Value

Matrix var[longitude,latitude] ##' @details ...

# Examples

```
## Not run:
mydat<-readncdflvar('landmask8.nc')
## End(Not run)</pre>
```

readRegGridBin

Function that reads a regular global binary grid.

# Description

Function that reads a regular global binary grid.

#### Usage

```
readRegGridBin(filename, nx = 2880, ny = 1440, res = 0.125, ...)
```

#### **Arguments**

filename	A character string with the file name.
nx	Number of rows in the grid (longitude). Deafault is nx=2880.
ny	Number of columns in the grid (latitude). Deafault is ny=1440.
res	The grid spacing in degrees. Default is res=0.125.

... Additional arguments to readBin.

tideConvert 19

#### **Details**

The default is grid is a 1/8 degree grid which is 2880 longitudes by 1440 latitudes: longitudes (0.5,1.5,2.5....2879.5)/8 degrees, latitudes -90 + (0.5,1.5,2.5....1439.5)/8 degrees. The type is real\*4, hence the length of the file i 4\*nx\*ny. The unit is meter.

#### Value

An object of the type coastMDT; a list containing a matrix g[lon,lat], a vector lon (longitudes) and a vector lat (latitudes).

tideConvert

Function for converting between different permanent tide systems.

#### **Description**

Function for converting between different permanent tide systems.

#### Usage

```
tideConvert(phi, convtype, k = 0.3)
```

# **Arguments**

phi The latitude in degrees.

convtype A character string giving the type of conversion. The legal strings are; 'MT2ZT',

'ZT2MT', 'ZT2TF', 'TF2ZT', 'MT2TF', and 'TF2MT'. Here, MT is mean tide,

ZT is zero tide and TF is tide free (or nontidal)

k is a love number, the default value is k=0.3

#### **Details**

The conversion expressions are based on Ekman, 1989. The correction must be added.

#### Value

The conversion correction; An array of height differences in meters.

20 wgs2topCorr

wgs2topCorr

Function that estiamtes the height difference between WGS84 and Topex ellipsoids

# Description

Function that estiamtes the height difference between WGS84 and Topex ellipsoids

# Usage

```
wgs2topCorr(phi)
```

# Arguments

phi

The latitude in degrees.

#### **Details**

•••

#### Value

An array with the height differences.
